

Executive Summary

The dashboard indicates that **employee stress levels are relatively high**, with an average stress score of approximately **7.64**, which is significantly above the target stress level of 5. This suggests workforce wellbeing is a concern and intervention may be required.

The analysis also shows a clear relationship between:

- Higher burnout frequency
- Lower job satisfaction
- Increased turnover intention

These findings align with the objectives of the healthcare workforce mental health study.

1. KPI Card: Average Stress Level

Observation

- Average Stress Level = **7.64**
- Target = **5**
- Performance = **154.77% of target**

Interpretation

Employees are experiencing stress levels substantially higher than the desired organizational target.

Since stress is one of the strongest predictors of burnout and turnover, this suggests the workforce is operating under significant pressure.

2. Burnout Frequency Donut Chart

Observation

Approximate distribution:

Burnout Frequency Employees

Often	44.25%
Occasionally	38.82%

Burnout Frequency Employees

Never 16.76%

Interpretation

Nearly half of all employees report experiencing burnout often.

Only a small proportion report never experiencing burnout.

This indicates burnout is widespread rather than isolated to a few individuals.

Business Meaning

Management should treat burnout as an organizational issue rather than an individual issue.

3. Average Stress by Department

Observation

Highest stress levels appear in:

1. ICU
2. General Practice
3. General Medicine

Lowest stress levels appear in:

- Administration
- Laboratory
- Radiology

Interpretation

Frontline clinical departments experience significantly higher stress than administrative departments.

This makes sense because ICU and General Medicine staff typically face:

- Higher patient volumes
- Critical care responsibilities
- Longer working hours

Recommendation

Focus wellness programs and staffing improvements on ICU and General Medicine first.

4. Average Job Satisfaction by Burnout Frequency

Observation

Job satisfaction decreases as burnout increases.

Approximate pattern:

Burnout	Satisfaction
Never	Highest
Occasionally	Medium
Often	Lowest

Interpretation

Employees who experience burnout frequently are much less satisfied with their jobs.

This is one of the strongest findings in your dashboard.

Business Meaning

Reducing burnout is likely to improve employee satisfaction and retention.

5. Average Stress Level by Workplace Factor

Observation

Highest stress contributors:

1. Heavy Workload
2. Work-Life Imbalance
3. Safety Concerns

Lower contributors:

- Career Stagnation
- Understaffing
- Job Insecurity

Interpretation

Heavy workload is the leading driver of employee stress.

This is consistent with healthcare environments where employees often work long shifts under demanding conditions.

Recommendation

Management should investigate:

- Staffing levels
 - Shift scheduling
 - Workload distribution
-

6. Turnover Intention Scatter Plot

Observation

The "Yes" turnover group appears clustered at:

- Higher stress levels
- Higher combined stress/absence measures

while the "No" group shows lower values.

Interpretation

Employees considering leaving their jobs tend to have higher stress-related indicators.

This suggests stress is strongly associated with turnover intention.

Business Meaning

Employees experiencing the highest stress are also the most likely to leave.

This creates a workforce retention risk.
